

Divide and Conquer Algorithms

Drawing a Ruler

Problem: Draw marks at regular intervals on a line

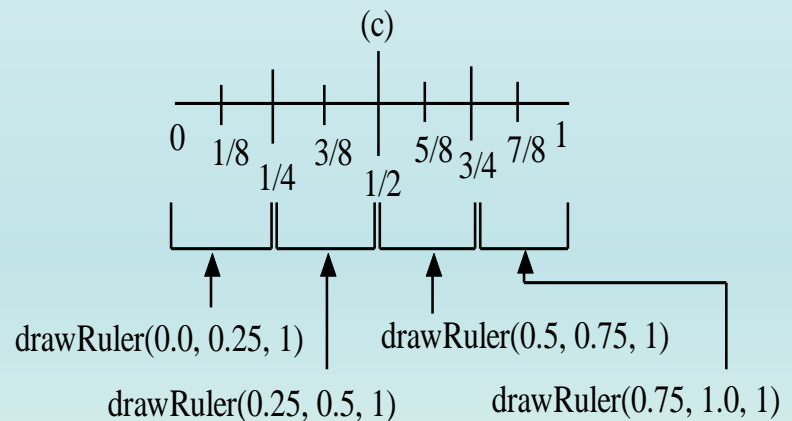

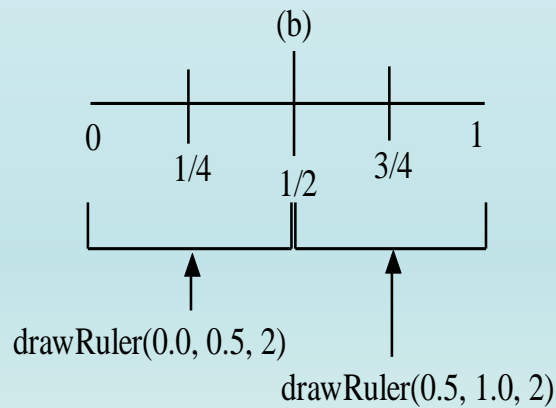

Write recursive

drawRuler (xBegin, xEnd, height)

assuming

drawMark (xCoord, height) is written

and a height of 0 indicates no further divisions

Recursive Ruler

- drawRuler (begin, end, h)
 - Base case?
 - ...
- A *Divide and Conquer (and Combine)* algorithm
 - Split problem into subproblems
 - Solve subproblems
 - Combine solutions to subproblems to solve whole problem

Iterative Ruler

```
void
drawRuler (begin, end, incr)
{
    // Start edge
    drawMark (begin, END_HEIGHT);
    begin += incr;
    while (begin != end)
    {
        drawMark (begin, ?);
        begin += incr;
    }
    // End edge
    drawMark (end, END_HEIGHT);
}
```

Two Sorting Algorithms

- Divide and Conquer Sorting Algorithms

- Merge Sort

- Split in half (divide)
 - Sort halves recursively (conquer)
 - Merge sorted halves (combine)
 - *Worst = Average = $O(N \lg N)$*

- Quick Sort

- Choose pivot value from array
 - Place pivot in final position (divide)
 - Elements to left \leq pivot
 - Elements to right \geq pivot
 - Sort 2 sublists recursively (conquer)
 - Average = $O(N \lg N)$
 - *Worst = $O(N^2)$*

Merge Sort

```
void
mergeSort (int A[], size_t first, size_t last)
{
    if (last - first > 1) {
        size_t mid = first + (last - first) / 2;
        mergeSort (A, first, mid);
        mergeSort (A, mid, last);
        inplace_merge (A + first, A + mid, A + last);
    }
}
```

Merge Algorithm

- Merge sort requires *merge* algorithm
 - Complexity of merge?
- Out-of-place merge: merge (v, first, mid, last)
 - v[first, mid) sorted
 - v[mid, last) sorted
- Result: v[first, last) sorted

Call Tree for Merge Sort

Quicksort Code

```
void
quicksort (int A[], size_t first, size_t last)
{
    if (last - first > 1) {
        auto i = partition (A, first, last);
        // Pivot is placed in A[i]
        quicksort (A, first, i);
        quicksort (A, i + 1, last);
    }
}
```

Partition Routine

```
// will go into details later...
size_t
partition (int A[], size_t first, size_t last) {
    median3 (A, first, last - 1);
    int pivot = A[last - 2];
    size_t up = first, down = last - 2;
    for ( ; ; ) {
        while (A[++up] < pivot) { }
        while (A[--down] > pivot) { }
        if (up >= down) break;
        swap (A[up], A[down]);
    }

    swap (A[last - 2], A[up]);
    return up;
}
```

Quicksort

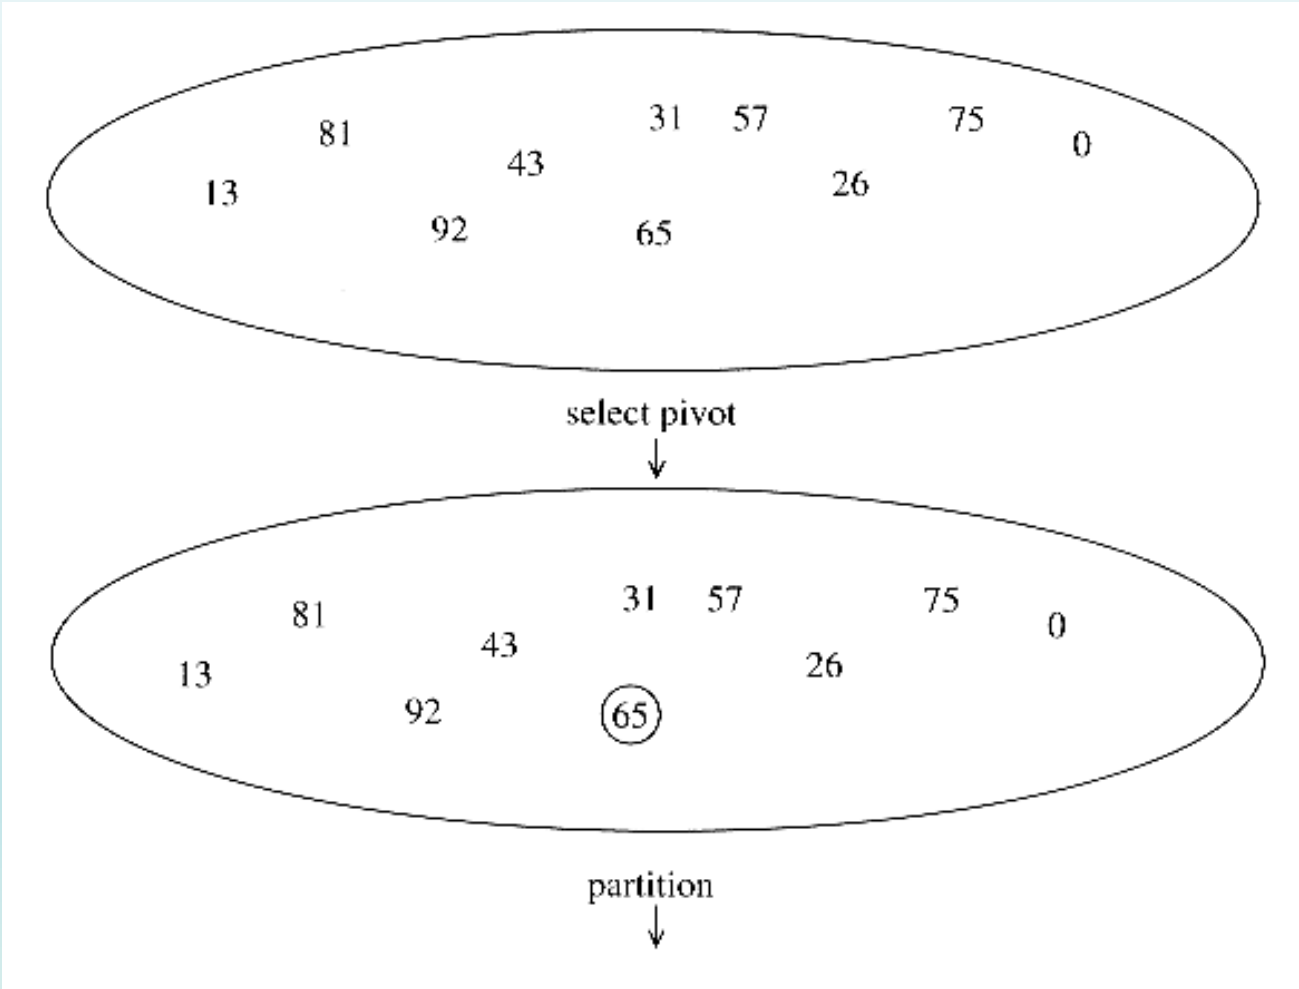

- *Fastest* known sorting algorithm in practice
 - Part of `std::sort`
 - May be used in `cstdlib qsort`
 - `qsort (void* base, size_t num, size_t size, int (*comp)(const void*, const void*))`
- Average case: $O(N \log N)$
- *Worst case*: $O(N^2)$

Quick Sort

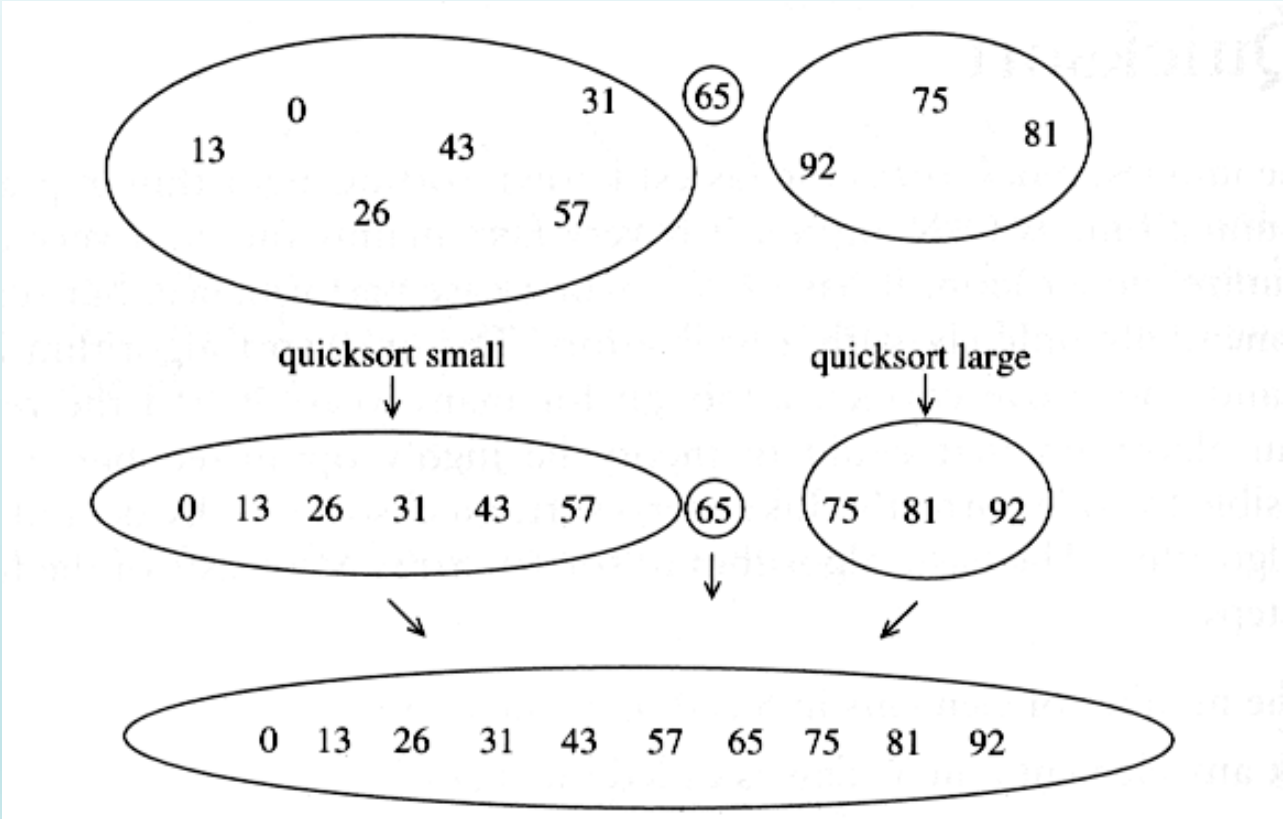

- Divide step
 - Pick any element (*pivot*) v in S
 - Partition $S - \{v\}$ into two disjoint groups
$$S1 = \{x \in S - \{v\} \mid x \leq v\}$$
$$S2 = \{x \in S - \{v\} \mid x \geq v\}$$
- Conquer step: recursively sort $S1$ and $S2$
- Combine step: list the sorted $S1$, followed by v , followed by sorted $S2$

Quick Sort...

Quick Sort...

Partitioning

- Partitioning
 - Key step of quicksort algorithm
 - Many ways to implement
- How to pick pivot will be discussed later

Partitioning Strategy

- Want to partition an array $A[\text{left} \dots \text{right}]$
- Swap pivot and $A[\text{right}]$
- Let $i = \text{left}$; $j = \text{right} - 1$

Partitioning Strategy

- Want to have

- $A[k] \leq \text{pivot}$, for $k < i$
- $A[k] \geq \text{pivot}$, for $k > j$

- While $i < j$

- Move i right, skipping over elements smaller than pivot
- Move j left, skipping over elements greater than pivot
- When both i and j have stopped
 - $A[i] \geq \text{pivot}$
 - $A[j] \leq \text{pivot}$

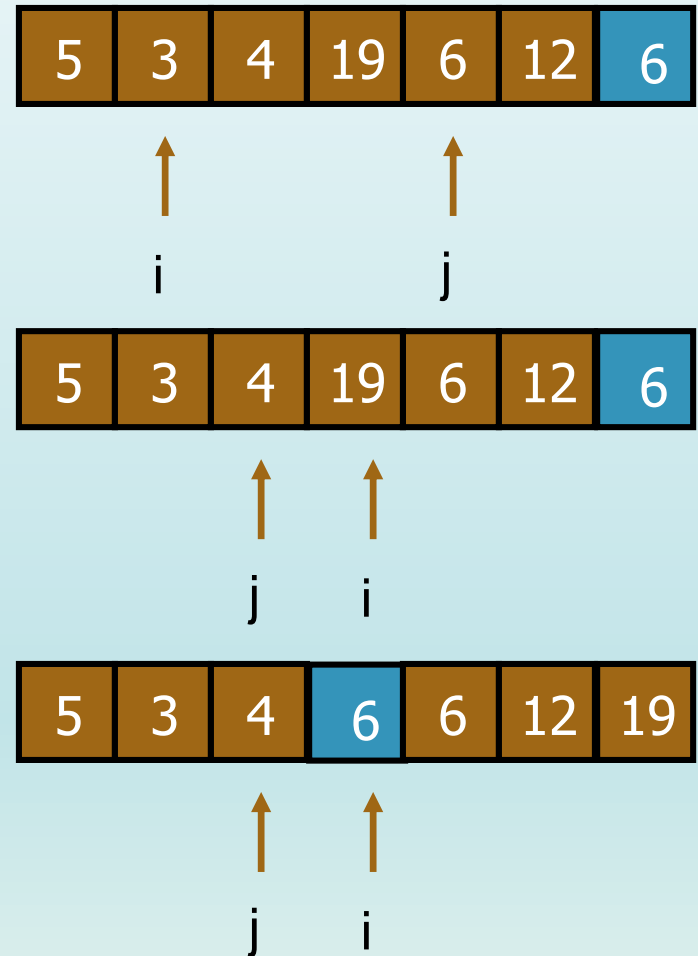

Partitioning Strategy

- When i and j have stopped and i is to the left of j
 - Swap $A[i]$ and $A[j]$
- After swapping
 - $A[i] \leq \text{pivot}$
 - $A[j] \geq \text{pivot}$
- Repeat the process until i and j cross

Partitioning Strategy

- When i and j have crossed
 - Swap $A[i]$ and pivot
- Result
 - $A[p] \leq \text{pivot}$, for $p < i$
 - $A[p] \geq \text{pivot}$, for $p > i$

Small arrays

- Cutoff value for small arrays
- Depends on
 - Time to make a recursive call
 - Architecture
 - Compiler
 - Other factors

Picking the Pivot

- Use the first element as pivot
 - OK if the input is random
 - What happens if the input is already sorted?
 - Can result in $O(N^2)$ behavior
- Choose the pivot randomly
 - Generally safe
 - Random number generation can be expensive

Picking the Pivot

- Use the median of the array
 - Partitioning always cuts the array into roughly half
 - An *optimal* quicksort ($O(N \log N)$)
 - How do you find the median?

Pivot: Median of Three

- Compare just three elements: the leftmost, rightmost and center
- Swap these elements if necessary so that
 - A[left] = Smallest
 - A[right] = Largest
 - A[center] = Median of three
- Pick A[center] as the pivot
- Swap A[center] and A[right - 1] so that pivot is at second-to-last position

median3

```
int center = ( left + right ) / 2;
if( a[ center ] < a[ left ] )
    swap( a[ left ], a[ center ] );
if( a[ right ] < a[ left ] )
    swap( a[ left ], a[ right ] );
if( a[ right ] < a[ center ] )
    swap( a[ center ], a[ right ] );

// Place pivot at position right - 1
swap( a[ center ], a[ right - 1 ] );
```

Pivot: median of three

$A[\text{left}] = 2$, $A[\text{center}] = 13$,
 $A[\text{right}] = 6$

Swap $A[\text{center}]$ and $A[\text{right}]$

Choose $A[\text{center}]$ as **pivot**

↑
pivot

Swap pivot and $A[\text{right} - 1]$

↑
pivot

Only need to partition $A[\text{left} + 1, \dots, \text{right} - 2]$. Why?

Main Quicksort Routine

```
if( left + 10 <= right )  
{
```

```
    Comparable pivot = median3( a, left, right );
```

Choose pivot

```
        // Begin partitioning
```

```
        int i = left, j = right - 1;  
        for( ; ; )  
        {  
            while( a[ ++i ] < pivot ) { }  
            while( pivot < a[ --j ] ) { }  
            if( i < j )  
                swap( a[ i ], a[ j ] );  
            else  
                break;  
        }
```

Partitioning

```
        swap( a[ i ], a[ right - 1 ] ); // Restore pivot
```

```
        quicksort( a, left, i - 1 ); // Sort small elements  
        quicksort( a, i + 1, right ); // Sort large elements
```

Recursion

```
    }  
    else // Do an insertion sort on the subarray  
        insertionSort( a, left, right );
```

For small arrays

Partitioning Part

- Works only if pivot is picked as *median-of-three*
 - $A[\text{left}] \leq \text{pivot}$ and $A[\text{right}] \geq \text{pivot}$
 - Thus, only need to partition $A[\text{left} + 1, \dots, \text{right} - 2]$
- j will not run past the end
 - because $A[\text{left}] \leq \text{pivot}$
- i will not run past the end
 - because $A[\text{right}-1] = \text{pivot}$

```
int i = left, j = right - 1;
for( ; ; )
{
    while( a[ ++i ] < pivot ) { }
    while( pivot < a[ --j ] ) { }
    if( i < j )
        swap( a[ i ], a[ j ] );
    else
        break;
}
```

Quicksort vs. Mergesort

- quicksort and mergesort are $O(N \log N)$ in the average case
- Why is quicksort *faster* than mergesort?
 - Inner loop
 - No extra juggling as in mergesort

```
int i = left, j = right - 1;
for( ; ; )
{
    while( a[ ++i ] < pivot ) { }
    while( pivot < a[ --j ] ) { }
    if( i < j )
        swap( a[ i ], a[ j ] );
    else
        break;    inner loop
}
```

Analysis

- Assumptions
 - A random pivot (no median-of-three partitioning)
 - No cutoff for small arrays
- Running time
 - pivot selection: constant time $O(1)$
 - partitioning: linear time $O(N)$
 - running time of two recursive calls
- $T(N) = T(i) + T(N - i - 1) + cN$ where c is a constant
 - i : number of elements in S_1

Worst-Case Analysis

- What will be the worst case?
 - Pivot is smallest element, all the time
 - Partition is always unbalanced

$$T(N) = T(N - 1) + cN$$

$$T(N - 1) = T(N - 2) + c(N - 1)$$

$$T(N - 2) = T(N - 3) + c(N - 2)$$

⋮

$$T(2) = T(1) + c(2)$$

$$T(N) = T(1) + c \sum_{i=2}^N i = O(N^2)$$

Best-case Analysis

- What will be the best case?
 - Partition is perfectly balanced
 - Pivot is always in the middle (median of the array)

$$\begin{aligned}T(N) &= 2T(N/2) + cN \\ \frac{T(N)}{N} &= \frac{T(N/2)}{N/2} + c \\ \frac{T(N/2)}{N/2} &= \frac{T(N/4)}{N/4} + c \\ \frac{T(N/4)}{N/4} &= \frac{T(N/8)}{N/8} + c \\ &\vdots \\ \frac{T(2)}{2} &= \frac{T(1)}{1} + c \\ \frac{T(N)}{N} &= \frac{T(1)}{1} + c \log N \\ T(N) &= cN \log N + N = O(N \log N)\end{aligned}$$

Efficiency of Quick Sort

- Best and worst case recurrences

- Another way to solve them

- Best

- $T(N) = 2 * T(N/2) + N; T(1) = 1$

- $T(N) = 2 * (2 * T(N/4) + N/2) + N$

- $= 2 * (2 * (2 * T(N/8) + N/4) + N/2) + N$

- $= 2^k * T(N/2^k) + k * N$

- $k = \lg(N) \rightarrow T(N) = N * T(1) + \lg(N) * N$

- $= O(N \lg(N))$

- Worst

- $T(N) = T(N-1) + N; T(1) = 1$

- $T(N) = ?$

Average-Case Analysis

- Difficult
- Average running time is $O(N \lg N)$

Finding k^{th} Smallest Element

- Compute k^{th} order statistic
 - $k = 1$ is min
 - $k = N$ is max
- Partition based on some pivot value
 - $i = \text{partition}(A, \text{left}, \text{right})$
 - if i matches k return $A[i]$ // Assuming 1-based
 - Recurse on left if $k < i$
 - Recurse on right if $k > i$
 - Find $(k - i)^{\text{th}}$ smallest
